If the empirically observed properties of the solar convective zone are successfully represented by such a model, the time dependence of other parts of the solar cycle will have to be explained. In particular, the usual “butterfly” shape of the activity seems to be a reflection of the gravity mode pattern in a rapidly rotating star, whereas the phase transition observed in this study can be understood only as a result of the instability growth, which is inherently non-linear. Although the mechanism of the dynamo origin, which is related to rotation, is not yet understood, it seems to be universally present throughout the main-sequence. A thorough theoretical

analysis of the influence of rotation on the dynamo mechanism is required. A more detailed study of the solar evolution is also necessary in the context of the dynamo models. We would like to thank Y. Osaki for providing us with the universal  $g$ -mode solution with constant  $l$ . B.
